

Housing for a Changing Climate: The Commonwealth Environmental Building Station in 1950s Australia

Rachel Goldlust

Summary

Historically, understanding climate as a function of technology and design has not been critical to developing government policy in Australia. Postwar reconstruction, however, involved a radical departure from a reliance on conventional and imported materials to consider earth as a desirable building material and construction method. Looking to adapt to, rather than control, local landscapes, the national housing agenda was briefly shaped by environmental awareness and climatic considerations.

Modern houses are increasingly designed to buffer us from the extremes of heat and cold. A belief held by both professionals and the public that a home can and should reflect the climate and location has waxed and waned over the twentieth century. However, research in housing adaptability has surprising origins. In a continent notorious for its extremes, the Australian government fostered an innovative center known as the Commonwealth Environmental Building Station (CEBS) in the immediate postwar period. Concerns about the environment led to an international drive to place a climatically defined framework over the layout and construction of homes. In Australia, government science linked technology, the environment, and domestic spaces by reviving the use of raw earth as a viable and adaptable building method.

Test huts in Mildura, circa 1946.

Following the Depression and two major wars, the wartime Labour government faced a housing crisis, building-material shortages, and a growing population. As the magnitude of the crisis became clear, the Ministry of Post-War Reconstruction created a Small House Bureau in 1944 to reinvigorate the housing landscape. One of its directors, the celebrated modernist architect Robin Boyd, took an interest in *pisé*, meaning "earth in place." Building with readily accessible local materials could help solve the housing crisis, Boyd wrote in his weekly newspaper column. It seemed reasonable to "make it of mud!" as earthen walls were "cheap, strong, weatherproof, and highly insulating."

In 1944, the Ministry also created CEBS, located on 40 acres north of Sydney, to develop its scientific prowess across a range of technical industries. The first chief technical officer, English architect and engineer George Middleton arrived soon after in 1947. Middleton also brought a European mindset that saw the use of raw earth as a rational, traditional, yet thoroughly modern, building solution. As one of several technical solutions being pursued, CEBS championed the investigation of the structural and thermal qualities of earth as a "novel and progressive" means of building.

The Station's mandate was to carry out experimental construction in different climatic and geographical locations and advise regulators, housing authorities, and government departments. Engineers, builders, architects, and the public welcomed this innovative approach to housing and applauded the growing recognition of the relationship between climate and house design across the nation's varied, extreme weather and seasonal conditions. One article from the *Cobram Courier* in 1949 exclaimed, "The fact that houses of similar design may be seen anywhere from Tasmania to Northern Australia, reveals the need for a more intelligent use of available building materials in alleviating the discomforts of climate."

With a focus on "heating, lighting, ventilation, insulation, sound and thermal transmission, and performance generally," CEBS's research sparked a transnational push across Britain and its colonial outposts to elevate building reconstruction to a scientific footing. Its novel contribution was to conceive of climatic zones and to test scaled experiments across different regions with variations of insulation, window size, and concrete versus timber floors, which resulted in extensive quantitative data sets that could be applied to other parts of the globe.

EBS's overall research output was extensive. Middleton's fascination with raw earth resulted in over one hundred technical studies, reports, and papers focusing on its adaptability to the Australian landscape and extremes. Providing a nexus for innovative scientific research with similar experiments being undertaken in New Zealand, the US and Canada, and the UK, CEBS conceived of and sought to unite the modern with the vernacular in a way that tried to be accessible and cost-effective. Before Middleton left to take a post with the United Nations in 1952, *Build Your House of Earth* was released and remains the authoritative text on rammed earth construction in Australia.

The Building Station continued to provide regulation and standards until its closure in 1981. The high-water mark had faded as labor costs became prohibitive throughout the 1960s, and regulation hurdles proved too costly for mainstream building works. Continuing to evolve and professionalize, earth building has risen and fallen in line with design trends and economics. It remains a rational, though still bespoke, housing style due to outdated regulation requirements, which prefer prefabricated materials such as rigid insulation, and a lack of collated data on the enduring ability of natural materials to provide thermal comfort. Though the use of earth only momentarily preoccupied the agenda of engineers and bureaucrats, the work of CEBS directly addressed the problem of building efficiency twenty years before the energy-conservation movement emerged across the globalized North.

With climate change resulting in more frequent and extreme weather events, the assertion that we should, as best practice, build our houses to suit the prevailing winds, chill factors, sun exposure, seasonal shifts, and climate

zone no longer seems radical. As we continue to struggle to build homes that can withstand the vagaries of a rapidly changing environment, Middleton's research, and the work of CEBS serves as a pointed reminder of the potential and capacity of earth, even in an extreme and varied climatic continent such as Australia. The contribution of the Station, then internationally recognized for its innovation and experimentation, has been forgotten and its establishment overlooked as a critical moment when technology, climate, and habitation were momentarily occupying the popular agenda. Building regulators, architects, designers, and engineers have ignored the warning by CEBS of the danger of disregarding "the prevailing climatic conditions, and to the irrational use of traditional materials," and generations of outmoded and inefficient housing stock reflect this oversight.

About the author:

Rachel Goldlust

Rachel Goldlust traces the history of self-sufficient living in Australia from the nineteenth century to the present. Her recently completed PhD thesis explores the social and environmental history of living off-grid as a way for urban dwellers in Australia to connect with the land. Before pursuing her PhD, Rachel undertook a master's degree in social sciences focusing on sustainable planning. She then worked as a municipal-town planner and taught sustainability and environmental education. Rachel is passionate about oral history, environmental and social justice, travel, storytelling, and bringing sustainable-living ideas to wider audiences through her work and writing.
