

What Is a Fungus? Mycology's Dada Moment

Nathan Smith

Summary

What do an early twentieth-century art movement and mycological taxonomy have in common? As it turns out, quite a bit. This article explores Richard William George Dennis's notorious mycological hoax, in which he described a golf ball as a new species of fungus, within the wider context of mycological taxonomy and examines the impact the publication on the species continues to have on our understanding of what, and who, makes a species.

In arguably the most defining moment of Dadaist art, Marcel Duchamp (1887–1968), under the pseudonym R. Mutt, submitted *Fountain*, a mass-produced urinal, to the inaugural exhibition of the Society of Independent Artists to be displayed at the Grand Central Palace in New York in 1917 (Figure 1). When the original was rejected for display and subsequently lost, it did not matter; Duchamp merely put his name to other urinals. Neither the object nor the process mattered—an object became art through the signature of the artist alone.

A similar event occurred in 1962, when Richard William George Dennis (1910–2003; Figure 2), Head of Mycology at Royal Botanic Gardens, Kew, published an article titled “A Remarkable New Genus of Phalloids in Lancashire and East Africa” in the *Journal of the Kew Guild*. The article describes the discovery of a new species submitted to the Kew Fungarium, a global center for fungal taxonomy, for identification by several collectors who, showing “praiseworthy modesty,” had chosen to remain anonymous. It had been found once in Lancashire, England, and several times in East Africa and closely resembled “certain small, hard but elastic, spheres enjoyed by the Caledonians in certain tribal rites,” with a distinct odor described as “old or heated India rubber.” The punch line, placed at the end of the article, occurs when, as is tradition, the species is formally described and is given the Latin binomial *Golfballia ambusta*.

The article followed a long line of mycological jokes and hoaxes. A previous mycologist at Kew, George Edward Masee (1845–1917), was known to deliberately, and playfully, take highly contradictory mycological and scientific views to “stir up the hornet’s nest.” He also produced several questionable recordings of species new to Britain and self-confessed (though never publicly) to fabricating several fungal illustrations supposedly drawn from life. Across the pond, Curtis Gates Lloyd (1859–1926) recruited the alias of Professor McGinty to maliciously describe new species—with both the character and his publications working as a form of “disrespectful satire” toward mycologists that Lloyd disagreed with.

But Dennis went further than a hoax article. He maintained several collections of the “fungus” and curated and deposited them in the Kew Fungarium amongst the genera *incertae sedis* (a term applied to organisms whose relationship to other species is unknown). The “fungi” were formally accessioned (Accession Numbers K(M)230939–K(M)230941; Figures 3 and 4) and validly published in a printed journal. The result is that both to the outside observer and according to the rules and recommendations of the then-current version of the *International Code of Nomenclature for Algae, Fungi, and Plants*, *Golfballia ambusta* is a legitimate species.

In contrast to previous mycological hoaxes, Dennis’s claim was not to have discovered a species where one did not exist or expand the range of known fungi. Rather, in true Dadaist fashion, Dennis challenged (and undermined) the very understanding of what a fungus is by declaring that a fungus was whatever a mycologist decided it to be; any object was made a fungus through the signature of a mycologist alone.

Such a claim is particularly important in mycology, where the definition of a fungus is both hazy and in flux. Whilst the uppercase Fungi exists, representing the formal and genetically distinct Kingdom of Fungi, the more common understanding of (lower-case) fungi encapsulates a broad range of unrelated organisms that are “fungal-like.” Several mycologists, including Nicholas Money, have argued that organisms such as slime molds and oomycetes may all be considered fungi because they have many similar physiological processes and, in a rather circular logic, because they are “micro-organisms studied by mycologists.” Other organisms, such as the unicellular microsporidia, sit on the thresholds of the Kingdom and are designated Fungi depending on prevailing understandings and opinion of the earliest-diverging groups of the Fungal tree of life. Neither Fungi nor fungi, then, are fixed or easily definable. As such, while Dennis’s concept *Golfballia ambusta* may be provocative, it is a struggle to explain what exactly it offends.

Duchamp conceived *Fountain* partially to challenge the exhibition’s organizers, who claimed that all art submitted to them would be displayed—a claim ultimately proven false. The power of *Fountain* thus came, in part, from its ability to expose hypocrisy in artistic movements and to force a definition of what was, and was not, art—allowing the boundaries to be challenged. *Golfballia ambusta*, in equally playful fashion, exposes the variable premises of identification in mycology.

Less playful, perhaps, are recent attempts by some mycologists to move toward the descriptions of new fungal species through genetic sequence alone. This not only presents numerous technical issues but also more social ones regarding the accessibility of mycology to amateur participants. In trying to describe DNA-only species, several mycologists appealed to rules in the *Code* that allowed an illustration to substitute the presence of a

physical specimen in describing a species—a rule primarily designed to grandfather in older descriptions—arguing that a genetic sequence functioned as an illustration. After all, if a golf ball can be a fungus, then surely a sequence of letters can be an illustration.

Such efforts were ultimately unsuccessful, with the *Code* being updated to render such attempts illegitimate, but both Dennis’s golf-ball fungus and the later attempts to redefine illustration have put a Dadaist conundrum at the heart of mycological taxonomy. If a mycologist may decide anything is a fungus, then it no longer matters what a species is. Instead, the more pertinent question to ask is: who is a mycologist?

About the author:

Nathan Smith

Nathan Smith is a researcher, curator, and educator with an interest in the history of mycology (the study of fungi) and mycologists. His work has focused on the origins of British mycology and how museums can best utilize their fungal collections. He is currently digitizing the collections in the Fungarium at Kew and exploring how mycology functioned in the context of empire.
